Altegro Website Change Summary

Date: 8 October 2026

Overview

This document summarises the completed improvements to the Altegro operations website and its supporting API.

Completed changes

Notifications and administration

- Added personal notification preferences for in-app and email alerts.
- Users can set a minimum severity and quiet hours.
- Added a modern Administration workspace with platform health, email-delivery status, and read-only robot-account visibility for platform administrators.
- Added a security-audit summary for administrators, covering review items, access events, and controlled changes.

Reports and analytics

- Added PDF download for operations reports alongside CSV and JSON exports.
- Kept scheduled email reports with delivery status, pause/resume, and send-now controls.
- Updated predictive maintenance into AI-assisted maintenance recommendations based on fleet telemetry, recent errors, battery signals, and maintenance schedules.
- Recommendations are advisory and do not issue robot commands.

Operations and maintenance

- Added a monthly maintenance calendar showing active service due dates and their urgency.
- Improved the mobile dashboard with a compact priorities card that directs users to alerts needing attention.

Customer experience

- Added a read-only Customer Portal with customer-scoped fleet health, service status, maintenance risk, battery level, and site-level fleet summaries.
- The portal uses existing tenant, organization, role, and robot-scope authorization.

Appearance and languages

- Added a saved dark-mode preference.
- Added French as an additional language option alongside English and German.
- Continued responsive layouts for phone, tablet, and desktop use.

Security notes

- Customer-facing views are read-only.
- Maintenance recommendations remain decision support for qualified technicians.
- Passwords, session tokens, provider credentials, and protected diagnostics are never displayed in the new views.

Recommended next steps

1. Add OIDC single sign-on and multi-factor authentication, then replace prototype accounts with managed user memberships.
2. Finish moving the remaining legacy pages into the typed frontend and validate each role's key tasks with users.
3. Expand the customer portal with customer-approved reports, document access, and support-ticket tracking.
4. Add a read-only live fleet map with site and floor-plan context.
5. Complete production hardening: multi-instance database writes, durable event delivery, backup-restore drills, and independent security testing.
6. Validate CRM, service-desk, and robot-provider integrations with approved sandbox credentials and real contract tests.

Verification

- Server syntax checks passed.
- Backend regression tests passed for the prior completed API changes.
- TypeScript checking was run with the workspace configuration; the production frontend build requires Node.js 20.9 or newer.
